

# Why is resilience ecology a social science?

## Don Falk

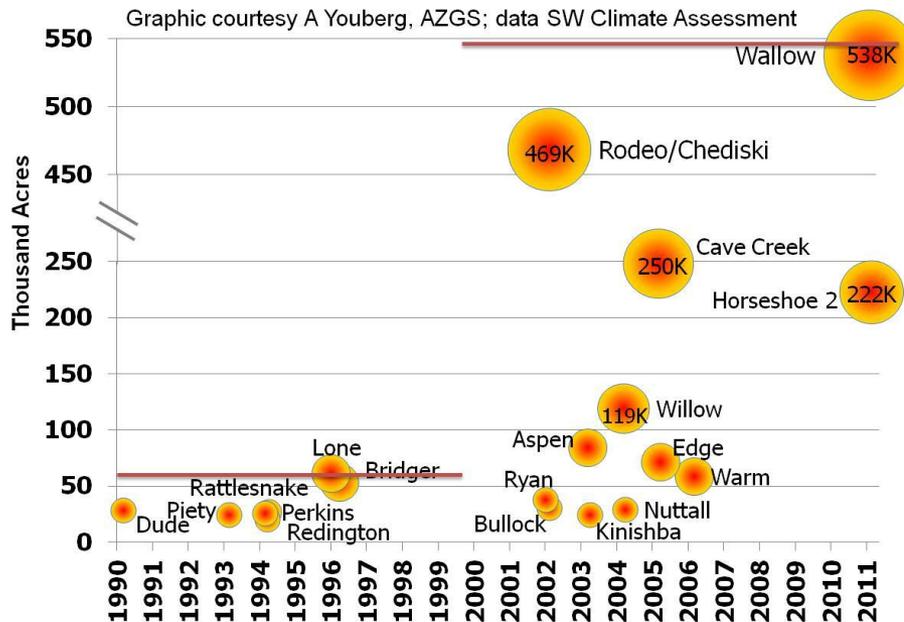

**1. Severe disturbance is both an ecological response and a multiplier of other drivers, leading to instantaneous change and strong feedbacks**

Near-total overstory tree mortality and large ( $10^4$  ac) high-severity patches, 2011 Las Conchas Fire, Jemez Mountains, NM

## 2. Wildfire is a major wild card in ecological change, and largely the outcome of our land-management decisions and effects on climate

Largest Arizona Wildfires, 1990-2012 (SWCC Historic Data)

2006 Nuttall-Gibson Complex, Pinaleño Mts.

Wildfire sizes courtesy Ann Youberg, AZGS

3. The consequences of extreme degradation are social and economic, not merely ecological

**Aug, 2011, post Las Conchas Fire, NM. Photo: CD Allen, USGS**

4. Even in a changing world, many of the reasons ecosystems are pushed beyond their limits are the "old" causes of degradation

Titeux et al. 2016

**5. Ultimately, we need to map the ecology of resilience onto ecosystem restoration and management – a social activity.**

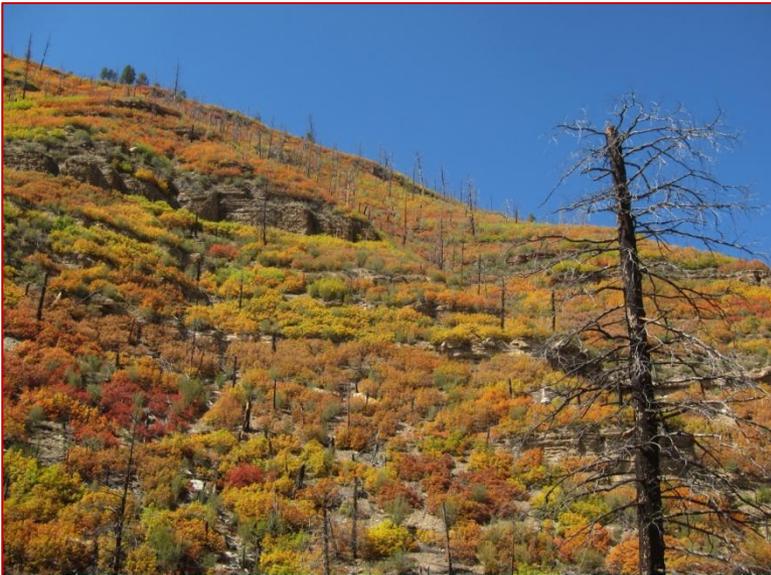

- Promote **resistance and persistence**
- Increase **recovery capacity**
- Assist ecosystems to **respond and reorganize**

Millar et al. 2007; Falk & Millar 2016

# Ecological tipping points

1. Generally initiated by some **combination of climate stress, ecological interactions, and disturbance**
2. System moves into a **new metastable state** (e.g. forest to shrub- or grass-dominated ecosystem)
3. System is then **resilient in its new state**.

Same toolbox, different times and places?

**From restoration to a  
resilience framework  
for ecosystem  
management**

**Do we fight or fold?**

Not all stasis is **adaptive**; not all **change** is bad. Can we make the distinction?

Do we understand the **mechanisms of persistence, recovery, and reorganization** that govern ecological trajectories?

Can we **use restoration to expand the resilience space** in which ecosystems can adapt in rapidly changing environments?

Resilience ecology means accepting (and even promoting) adaptive change

1. Which kinds and degrees of **change** are **adaptive**, and which are **destructive** of biodiversity and ecosystems?
2. Can we anticipate ecological consequences well enough to inform **decisions and actions on the ground**?
3. Are we prepared to **let go of some current ecosystems**, or would doing so violate our core principles?
